

How to store energy from photosynthetic power generation

Overview

After absorbing energy from the sun, plants convert it into chemical energy through photosynthesis, which is stored as ATP for plant use and excess energy. The process occurs primarily in the chloroplasts of plant cells, where chlorophyll absorbs light energy.

The conversion of solar energy into electrical current by photosynthetic organisms has the potential to produce clean energy. Life on earth depends on photosynthesis, the major mechanism for biological conversion of light energy into chemical energy. Indeed, billions of years of evolution and.

Photosynthesis is the process plants and some algae use to convert light energy to chemical energy stored as sugar within chloroplasts — the energy factories found in plant cells. Plants need only carbon dioxide and water for photosynthesis to work. Chloroplasts are full of chlorophyll, a green.

While efficient methods of clean energy storage remain elusive, Aspuru-Guzik is working with Michael Aziz, the Gene and Tracy Sykes Professor of Materials and Energy Technologies at Harvard's School of Engineering and Applied Sciences, and Roy Gordon, the Thomas Dudley Cabot Professor of Chemistry.

Photosynthesis is a crucial process that plants use sunlight, water, and carbon dioxide to create oxygen and energy in the form of sugar. This process is essential for the existence of most life on Earth, as it converts sunlight into chemical energy, allowing plants to carry out essential life.

Plants are able to store light energy through a process called photosynthesis. This process involves the conversion of light energy into chemical energy, which is then used to synthesise glucose and oxygen from carbon dioxide and water. The light-dependent reaction occurs within the thylakoid.
