

Solar geothermal energy storage

Overview

What is geothermal battery energy storage?

This is particularly important as solar and wind power are being introduced into electric grids, and economical utility-scale storage has not yet become available to handle the variable nature of solar and wind. The Geothermal Battery Energy Storage concept uses solar radiance to heat water on the surface which is then injected into the earth.

Why is thermal storage important for a geothermal/solar hybrid plant?

Thermal storage enables energy from the hybrid plant to be time-shifted to periods in the day where utility market demand and energy rates are higher. The objective of this project is to identify cost-effective thermal storage systems for a geothermal/solar hybrid system in order to increase the plant dispatchability.

What is a geothermal reservoir?

A concept to store large amounts of renewable energy daily to seasonally. Reservoir characteristics for a geothermal battery system. The conversion of solar or wind to geothermal electricity. Subsurface sedimentary basin formations for large-scale hot water storage. Solar heat collection to create a high-temperature geothermal reservoir.

Can geothermal energy storage be used in large-scale energy storage?

The Geothermal Energy Storage concept has been put forward as a possibility to store renewable energy on a large scale. The paper discusses the potential of UTES in large-scale energy storage and its integration with geothermal power plants despite the need for specific geological formations and high initial costs.

What are the advantages of geothermal energy?

The main advantages of geothermal energy are its low cost and its ability to

operate year-round at high capacity factors. This allows it to provide firm, dispatchable electricity and, if incentivised, ancillary services to the electricity system. As the penetration of solar and wind power grows, these characteristics become more valuable.

Where is shallow geothermal energy stored?

Shallow geothermal energy is stored in the Earth's uppermost layers, up to a few hundred meters deep, and can be extracted using a geothermal heat exchanger or ground source heat pump (GSHP). The heat exchanger is placed 1 to 2 m below the surface from the shallow geothermal energy.
